Abstract

\textit{Mucuna pruriens} and \textit{Canarium schweinfurthii} used in traditional medicinal practices in Northern Nigeria, for the treatment of worms infestation were investigated. The \textit{in-vitro} anthelmintic evaluation of the crude and solvent partitions extracts, on \textit{Pheretima posthuma} and \textit{Acaris suum} (eggs and L\textsubscript{2} stage) respectively. Showed that the hexane fraction (leaves and stem bark) of \textit{Canarium schweinfurthii} and \textit{Mucuna pruriens} (leaves) had ovicidal potency of (100.00 ±0.33) at 80mg/ml. While the Chloroform fractions showed ovicidal activity of 98.20±0.12 and 98.20±0.12 80 mg/ml on the two plants respectively. The results of determination of larvicidal potency showed that the hexane fraction (0.06%) was the most potent, followed by the Chloroform fractions (0.1 and 0.2 % respectively). These results clearly justified the uses of these plants in the treatment of worms in ethno-medicinal practices.

Keywords: anthelmintic activity, mucuna pruriens, canarium schweinfurthii, pheretima posthuma, a. suum, eclodibility

INTRODUCTION

Helminth infections are among the most widespread infections in humans, distressing a huge population of the world. The majority of infections due to helminthes is generally restricted to tropical regions and cause enormous hazards to health and contributes to the prevalence of malnourishment, anemia, eosinophilia and pneumonia \cite{1}. Ever since the advent of broad-spectrum anthelmintics in the 1960's, anthelmintics of the macrocyclic lactone family have a significantly longer residual effect in comparison with the other anthelmintics.

Over time, questions have been raised concerning the long-term impact of the massive application of these highly efficacious, broad-spectrum anthelmintic compounds on the environment. Due to the bioavailability of some of these drugs, high percentages of these substances are being excreted unchanged after oral or systemic administration \cite{2,3}. To this day however, we remain oblivious to what the possible long-term ecological effects of these drugs and their residues are on pasture fauna and flora \cite{4}. The gastro-intestinal helminthes are becoming resistant to both the benzimidazole and macrocyclic lactone which are the available anthelmintic, therefore there is a foremost problem in treatment of helminthes diseases \cite{5}. This concern, among others, is stimulating the need for alternative, more biological measures of parasite control. Hence there is an increasing demand towards new anthelmintics, which may take time before they become less effective.

In biological farming, the use of traditional synthetic drugs is not allowed and therefore, organic farmers prefer a phytopharmaceutical approach for the control of parasitic infections on their farm \cite{6}. Nevertheless, continued efforts could be made to standardize the plant extracts with good anthelmintic activity and formulate best alternative herbal preparations to replace or complement the synthetic drugs, which are currently in use.

\textit{M. pruriens} is a tropical legume known as velvet bean and devils bean. The genus Mucuna belongs to the family \textit{Leguminosae} and consists of 100 species of climbing vines and shrubs. The chemical compounds responsible for the itch is a protein, mucunain \cite{7} and serotonin. \textit{C. schweinfurthii} (Burseraceae), is a wild tree found mostly in Africa, which produces fruit similar to olives. It is commonly known as African elemi; incense tree, bush candle tree or purple canary tree \cite{8}. In Nigeria, the trees are found mostly in the north-central Nigeria which includes: Pankshin, Mangu, Barkin Ladi and Bokkos LGAs of Plateau state as well as Niger State \cite{9}. These plants have a wide reputation among natives of being curative for helminthiases like elephantiasis \cite{10}, intestinal worms, genito-urinary diseases, black tongue, round worm, gonorrhea and stomach disorders \cite{11}. Aim of this study is to establish the anthelmintic potential of \textit{M. pruriens} and \textit{C. schweinfurthii} of the crude extract on \textit{Pheritima posthuma} and partitioned crude on two stages of \textit{A. suum}. 

236
MATERIALS AND METHODS

Plants

The leaves of *M. pruriens* and *C. schweinfurthii* were procured from University of Ibadan Botanical garden and the Pankshin area of Jos, Plateau state respectively. The plant materials were identified and authenticated by the curator; Mallam Musa Mohammed in the Department of Biological Sciences, Ahmadu Bello University Zaria, Kaduna State. Voucher numbers of 392 and 7232 were deposited for *M. pruriens* and *C. schweinfurthii* respectively.

Extraction of Mucuna pruriens and Canarium schweinfurthii

The powdered plant materials were extracted with methanol using both the soxhlet and maceration method. Crude extract of *M. pruriens leaves and C. schweinfurthii leaves* and bark were subjected to column fractionation with solvent of different polarity starting with n-hexane, chloroform, ethylacetate and methanol, in order of increasing polarity. The different solvent fraction obtained were evaporated to dryness and subjected to bioassays.

Biological Assay

Helminthes

The helminthes were collected according to the method described by Jabbar et al. [15]. Briefly; *The P. pothuma and A. suum* were identified by Mallam Yusuf Magagi, Department of Veterinary medicine, Parasitology and Entomology, Ahmadu Bello University Zaria.

Anthelmintic Studies on Pherecma Posthuma

This was carried out according to the method described by Marie-Magdeleine [16], to establish the potency of the plant as claimed by the ethnomedicinal usage. The choice of *P. pothuma* is as a result of the anatomical similarity to that of the parasite.

Egg Hatch Assay

The egg hatch assay was conducted as published by McGaw et al., (2007) [17] and Bizimysera et al. (2006) [18]. The counted number of eggs in a 0.5 mL of egg suspension was pipetted into a 96-well microtitre plate. Wells 1 to 3 were used for *Mucuna pruriens leaves* experiments, well 5 to 7 for *Canarium schweinfurthii leaves* experiments, wells 9 to 11 for *Canarium schweinfurthii* bark and wells 12 to 14 were used for both negative and positive controls. In addition, 0.5 mL of plant extract at different concentrations of 10, 20, 40 and 80 mg/mL were added. A commercial anthelmintic drug Albendazole (Levamisole, Afrivet, South Africa) was used as the positive control at the same concentrations and DMSO water used as a negative control. All tests were repeated 3 times.

The plate was incubated under humidified conditions at 25°C temperature for 48 hours thereafter a drop of Lugol’s iodine solution was added to each well to stop further hatching. All unhatched eggs and L₃ larvae were then counted.

Inhibition percentages were calculated using a formula by Cala et al., 2012 [19]

\[
I(\%) = \frac{(E_{gt} + L_3) - L_3}{(E_{gt} + L_3)} \times 100
\]

Larval Development Assay

The larval development assay was conducted as described by Bizimysera et al., (2006) [15]. The counted number of eggs in a 0.5 mL of the egg suspension was put into each well in a 96-microtitre plate with a 100 μl of lyophilized penicillin-streptomycin to combat fungal growth. The contents of the wells were then mixed, and the plates placed in an incubator under humidified conditions at ambient temperature for 48 hours for incubation of the eggs. After 48 hours, 0.5 mL of the extracts of *Mucuna pruriens and Canarium schweinfurthii* as well as Albendazole (Levamisole, Afrivet, South Africa) as a positive control at 10, 20, 40 and 80 mg/mL were added to respective plates. The negative control plates received 0.5 mL of DMSO. All experiments were replicated three times. Incubation of the plates was continued for 21 days, after which all the plates were examined to determine the survival of larvae at different concentrations. All the L₃ stage larvae in each well were counted and a percentage inhibition of larval development was calculated using the formula (Cala et al., 2012) [20]:

\[
E(\%) = \frac{(L_1 + L_2 + L_3) - L_3}{L_1 + L_2 + L_3} \times 100
\]

RESULT AND DISCUSSION

The hexane partitioned crude of *C. schweinfurthii* (Engl) and the chloroform partitioned crude of *C. schweinfurthii* (Engl) are yellowish oil and white crystals containing tannins and, flavonoids and tannins respectively while ethylacetate and methanol indicates the presence of alkaloid, cardiac glycoside, tannins, saponins and flavonoids which are potential antinematocidal compounds [17].

In-Vitro Anthelmintic Activity of the Crude Extract on Pherecma Posthuma

The Soxhlet leave extract of *M. pruriens* (DC), *C. schweinfurthii* (Engl) and barks of *C. schweinfurthii* (Engl); time for paralysis at 10mg/ml were 14.75±0.71, 22.00±0.41 and 27.00±0.32 minutes, while death occurred at 22.00±0.41, 30.50±0.12 and 145.00±0.07, minutes respectively. Macerated leave extract of *M. pruriens* (DC), *C. schweinfurthii* (Engl) and *C. schweinfurthii* (Engl) barks, paralysis time at 10mg/ml were 7.50±0.11, 14.00±0.41 and 17.00±0.30 minutes, whereas death took place at 22.00±0.41, 66.00±0.31, 36.5±0.40 minutes respectively. The time for paralysis and death for
albendazole at 10 mg/ml were 15.00 ±0.50 and 35.00±0.40 minutes respectively.

The crude extracts of the plants showed a significant anthelmintic activity (Table 1). The macerated extract contains thermolabile compounds that are potential anti-nematodical agent which its biological activity have been lost or affected by heat.

Crude macerated and soxhlet extract of *M. pruriens* (DC) showed significant difference in the time for paralysis but no significant difference in the time for death; this indicates that both extracts contains different tegumental diffusing agent (Table I).

Alkaloids were absent in the soxhlet extract and research on HL60 tissue-culture cells have shown that some alkaloids block the narrow region of the channels, which subsequently cause muscle contractions in nematodes.

This leads to worm paralysis in a contractile state and, once rendered immobile, the worms are expelled. The crude macerated and soxhlet extracts caused death in 22.5±0.41 minutes, this is an indication that both extracts contains similar death-inducing compounds.

The macerated and soxhlet extracts of *M. pruriens* (DC) leaves contain more potent antinematodal agent than *C. schweinfurthii* (Engl) leave and bark extracts; and the positive control (Table 1). Generally the extracts obtained through the cold extraction procedure (maceration) are more potent compared to the extracts obtained by hot-continuous process. These indicate that the type of extraction and partitioned crude extract of *C. schweinfurthii* (Engl) leaves and bark and *Mucuna pruriens* (DC) yielded four, three and three partitioned crude respectively.

The most potent partition of *C. schweinfurthii* (Engl) leaves and bark, and leaves of *M. pruriens* (DC) are hexane, chloroform and chloroform partitioned crude respectively. There is no significant difference in the percentage inhibition of unembryonated eggs of *A. suum* for the *C. schweinfurthii* (Engl) leaves, *C. schweinfurthii* (Engl) bark and *M. pruriens* (DC) leaves at all concentrations for all the partition extract. The methanol partition crude of *C. schweinfurthii* (Engl) bark showed a very low activity (Fig II), which is an indication of the absence of ovicidal phytochemical agents (Table 2). The in-vitro test of all the partition crude ovicidal activity at all tested concentrations and caused complete lyses of the eggs. Statistical differences (P<0.05) were also observed among plant extracts.

The effect of the leaves and bark of *C. schweinfurthii* (Engl) and leaves of *M. pruriens* (DC) on the unembryonated *A. suum* egg are presented in Figure I-III and Table 2 as percentage inhibition. The methanol partitioned crude of *C. schweinfurthii* (Engl) bark showed a very low activity (Fig II), which is an indication of the absence of ovicidal phytochemical agents (Table 2). The in-vitro test of all the partition crude ovicidal activity at all tested concentrations and caused complete lyses of the eggs. Statistical differences (P<0.05) were also observed among plant extracts.

Temperature plays an important role on the anthelmintic activity of various crude plant extracts (Table 1). The effect of the leaves and bark of *C. schweinfurthii* (Engl) and leaves of *M. pruriens* (DC) on the unembryonated *A. suum* egg are presented in Figure I-III and Table 2 as percentage inhibition. The methanol partitioned crude of *C. schweinfurthii* (Engl) bark showed a very low activity (Fig II), which is an indication of the absence of ovicidal phytochemical agents (Table 2). The in-vitro test of all the partition crude ovicidal activity at all tested concentrations and caused complete lyses of the eggs. Statistical differences (P<0.05) were also observed among plant extracts.
The high activities of the partitioned crude are due to the presence of potential antinematocidal as reported in the work of Athanasiadou et al. [18], which target the unique molecular and physiological pathways of parasites.

**Effect of the extracts on the second stage (L2) of A.suum**

The bioactivity accounts for 20.06% of the total variance at P value are < 0.0001. If bioactivity has no effect overall, there is a less than 0.01% chance of randomly observing an effect on the ecldibility. As the concentration of the partitioned crude increases, it reduces the mean hatching rate. The increase concentration accounts for 77.65% of the total variance at P value is < 0.0001.
For all the extracts, percentage eclodibility was lower than 10% at all concentrations except for methanol column fraction of *C. schweinfurthii* (Engl) bark (Fig V). An increase in concentration was characterized by a decrease in eclodibility rate, and there was a significant difference (P>0.05) for the different concentrations tested. The most potent partitioned crudes showed a comparable potency with the reference drug, albendazole at all dose.

**CONCLUSION**

Non standardized procedures of extraction may lead to the degradation of the phytochemicals present in the plants and may lead to variations thus leading to the lack of reproducibility (Table 1). This information can better equip entho-medicinal practitioners better their practice and reduce the huge medical bills incurred in the treatment of this tropical infection and hence, alleviate poverty. The unembryonated egg of *A. suum* is the non-infectious stage of the parasite; the objective is to prevent the unembryonated eggs from developing into infectious embryo of *A. suum* (L1 stage). Overall, the column fractions of the *C. schweinfurthii* (Engl) and *Mucuna puriens* (DC) which were *in vitro* evaluated in the present study had ovicidal and larvicidal activities on *A. suum*, which are the stages of dissemination into the environment. The partitioned crudes were more ovicidal than the reference drug but showed similar larvicidal potential with the reference drug. It is thought that these extracts penetrate the eggshell and stop the development of un-embryonated eggs in the same way as albendazole \[19\]. The present *in-vitro* results suggest that the extracts could affect the biology of the parasitic eggs and larvae. Nonetheless, further, experiments are still on to isolate and characterize these anthelmintic compounds.
